

## Chem 431A-L18-F'07

admin: Online quiz deadline Chapt 4 Monday, Nov5  
no exceptions. If your computer didn't work, tough!

Last lecture:

- 1) Chou-Fasman Rules for 2° prediction
- 2) motifs, domains, 4° structure
- 3) oxygen-binding proteins (chapter 4)

Today: Quiz #5

- 1) Saturation curves for Mb and Hb
- 2) Hill coefficient – what it means
- 3) Cooperativity and Allosterity of Hb

<p><b>Oxygen binding proteins: Chapter 5</b></p> <p>Mb -function is to facilitate O<sub>2</sub> transport in the muscles.(rapidly respiring tissue need O<sub>2</sub> fast at certain times and diffusion isn't fast enough. Mb acts like a bucket brigade. Of course, aquatic animals use it too as O<sub>2</sub> storage. Spermwhale has 10x more mb than terrestrial animals.</p> <p>Mb + O<sub>2</sub> &lt;=&gt; MbO<sub>2</sub> K= [MbO<sub>2</sub>] / ([Mb][O<sub>2</sub>]) (=&gt; [MbO<sub>2</sub>] = [Mb][O<sub>2</sub>](K) )</p>	<p>K=affinity constant. saturation: θ = sites occupied/total sites available = fraction oxygenated= oxygenated/total=[MbO<sub>2</sub>]/{[Mb]+[MbO<sub>2</sub>]}</p> <p>=&gt; θ = [Mb][O<sub>2</sub>](K) / { [Mb] + [Mb][O<sub>2</sub>](K) }</p> <p>=&gt; θ = [O<sub>2</sub>]/{(1/K)+[O<sub>2</sub>]} (ranges 0 to 1)</p> <p>or, θ = P<sub>O<sub>2</sub></sub> / {(1/K)+ P<sub>O<sub>2</sub></sub> }</p> <p>at θ=0.5, .5 = P<sub>50</sub>/(1/K + P<sub>50</sub>) =&gt; 1/K = P<sub>50</sub></p> <p>It is often written as: θ = P<sub>O<sub>2</sub></sub> / {P<sub>50</sub>+P<sub>O<sub>2</sub></sub>}</p> <p>Because, (1/K) must be the P<sub>O<sub>2</sub></sub> at which θ=50%</p> <p>for Mb P<sub>50</sub> ≈ 4mm Hg</p> <p>Discuss: plot θ vs pO<sub>2</sub> - hyperbolic, show P<sub>50</sub>.</p>
---	---

<p>this represents hyperbolic curve (describe hyperbola)</p> <p>P<sub>O<sub>2</sub></sub> ≈ 30 mmHg for Hb in venules. so Mb nearly saturated! (Mb is strongly binding protein)</p> <p>show weakly binding protein!</p> <p>Hb changes from strong binding protein at high O<sub>2</sub> to weakly binding at low P<sub>O<sub>2</sub></sub>. sigmoidal curve. cooperative mechanism. Earliest attempts to explain were by Archibald Hill (1910): assumed 1 step:</p> <p>Hb + nO<sub>2</sub> -&gt; Hb(O<sub>2</sub>)<sub>n</sub> (ie infinite cooperativity).</p> <p>=&gt; θ = (P<sub>O<sub>2</sub></sub>)<sup>n</sup> / { (P<sub>50</sub>)<sup>n</sup> + (P<sub>O<sub>2</sub></sub>)<sup>n</sup> } known as Hill eqn.</p>	<p>can show by rearrangement:</p> <p>θ/(1-θ) = (P<sub>O<sub>2</sub></sub>)<sup>n</sup> / (P<sub>50</sub>)<sup>n</sup></p> <p>Hill plot based on taking logs of both sides:</p> <p>Log{ θ/(1-θ) } = n log P<sub>O<sub>2</sub></sub> - n log P<sub>50</sub>.</p> <p>plot y = mx + b =&gt; where slope is n (an integer representing the number of subunits).</p> <p>actual graph is diff: sometimes 1 sometimes 3. for ideally cooperative Hb, n = 4. Note that n cannot exceed the number of monomer subunits but can be less than it.</p>
